Web Front-End Development
React Deployment Instructions

<u>Deployment</u>
To deploy your React app to a server create a directory on the server where your React app will live. In this example I created a directory called "hello" in my react directory, making the full path http://creative.colorado.edu/~apierce/samples/react/hello

Add that path to your app's package.json:
"homepage": "https://creative.colorado.edu/~apierce/samples/react/hello",
- Make sure it's a complete url including http:// at the beginning
- Do not include a backslash "/" at the end of the url
- Make sure you edit the package.json file and NOT package-lock.json

Then in the terminal cntrl C to stop the current process.
Create a production build
```
npm run build
```

This will create a build folder. Copy all the files in that folder and FTP them to the directory you created (http://creative.colorado.edu/~apierce/samples/react/hello).
Browse to that path you should see your app.

Note you can't see the JavaScript source through view source.
